ABSTRACT

Studies have shown that pregnant women are vulnerable to malaria parasitemia. Unfortunately, less attention has been paid to the effect of age group on malaria parasitemia among this group of subjects. The aim of this study was to determine the most age vulnerable age group of malaria parasitemia among pregnant women. It was a hospital-based study carried out in two selected health institutions in Rivers State. A simple random sampling technique was used to select the areas of study as well as the 400 participants used for the study. A well-structured questionnaire was used to collect the socio-demographic data of the subjects within the age range of 21–40 years. Venous blood samples of the subjects were collected from the subjects and examined for the presence of malaria parasites using standard procedures. The results obtained from the health institution located in urban region of Rivers State (Braithwaite Memorial Specialist Hospital) showed the prevalence rate of 36.4% in the group within the age of 21-25 years, 36.1% among age range of 26-30 years, 22.5% for 31-35 years and 23.1% for the pregnant women within the age of 36-40 years. The results obtained from the health institution located at semi-urban region of the state (General hospital Bori) showed prevalence of 44.2%, 23.0%, 35.7% and 41.7% respectively. There was a significant difference the prevalence of malaria among the age groups in both health facilities, P= 0.0001. This study has shown that younger pregnant women especially those in their 20s are more prone to malaria parasitemia than older women in the Rivers State.

1. INTRODUCTION

The effects of malaria infection during pregnancy are of serious public health concern in the tropical and subtropical regions throughout the world [1]. Malaria is a serious health burden of developing nations, including Nigeria [2]. It is very simple to diagnose and treat, yet it claims more lives than any other infectious disease in the world [3]. Different risk factors for malaria among pregnant women were identified by previous studies. These include educational status [4], age [5], ANC visit, gestational age [6], parity [4], gravidity, and ITN utilization [7].

The Roll Back Malaria (RBM) was an initiative of the government that aimed to significantly reduce malaria deaths by 2015. The program became necessary, given the huge burden of malaria [3]. The key emphases of RBM are early detection and timely treatment of malaria, the detection, and control of epidemics, control of vectors using larvicide and bed nets treated with insecticide, and the prevention and treatment of malaria in pregnancy. Biolarviciding is the application of biological agents called larvicides to kill mosquitoes by destroying mosquito larvae and/or pupae. Vector control is necessary in order to greatly reduce cases of malaria infection by controlling the vector that is responsible for the transmission of the infection. In pregnancy, malaria infection is a major cause of morbidity and mortality in both the mother and her newborn baby. The situation is worse in first pregnancies as they are yet to develop immunity against Plasmodium falciparum, the major species that has been implicated. Uniquely, P. falciparum -infected red blood cells sequesterate in the placenta, causing maternal anaemia and intrauterine growth retardation or even fetal demise [8]. The two main methods used for achieving vector control are spraying of insecticides indoors and the use of Insecticide Treated Nets (ITNs). Almost a decade after the launch of RBM not much has been done in the aspect of the provision of ITNs and effective drugs [9].

Over 30 million women become pregnant in Africa annually and are at great risk of malaria infection especially from Plasmodium falciparum, and this can prove fatal for both mother and fetus [10]. Prevention of malaria in pregnancy is one of the main challenges of public health in Africa and also the priority for the Roll Back Malaria partnership. Effective management of malaria infections, use of Insecticide Treated Nets (ITNs), and, in areas of stable transmission, Intermittent Preventive Treatment (IPT) are the three major recommended approaches of the Roll Back Malaria program. This study therefore focused on assessing age group that is more vulnerable to malaria infection among pregnant women in Rivers State.

2. METHODS

2.1 Study Design

This was a cross-sectional study involving 400 pregnant women aged 21-40 years attending antenatal clinics in Braithwaite Memorial Specialist Hospital, Port Harcourt (BMSH) and General Hospital, Bori (GHB) both in Rivers State. Structured questionnaires were given to the pregnant women to obtain their demographic data. Subjects were grouped into four age groups: 20-25yrs, 26-30yrs, 31-35yrs and 36-40yrs.

2.2 Eligibility Criteria

The following subjects were recruited in the study; pregnant women between the age bracket of 21-40yrs registered and attending the antenatal clinics of both health facilities. In addition to these inclusion criteria, only subjects with signed consent form were also admitted into the study. On the other hand, pregnant women with fever, weakness, anorexia, those who have just taken anti-malaria drugs, and those who are HIV positive were excluded from the study.

2.3 Sample Size Determination

The sample size was determined using the formula of Araoye [11].

\[ n = \frac{Z^2 pq}{d^2} \]

- \( n \) = Sample size minimum
- \( Z \) = 95% confidence interval = 1.96
- \( p \) = Proportion of the target population = ?
- \( q \) = 1.0 - \( p \)
- \( D \) = Degree of accuracy (95% interval) = 0.05%

2.4 Sampling Method

Subjects were selected in a simple random method using a numbering system where subjects who picked “1” were selected and those that picked “0” were rejected [12,13]. After subjects were selected, the groups had the
following number of subjects; For BMSH, group 21-25yrs had 22 subjects; group 26-30yrs had 72 subjects; group 31-35yrs had 80 subjects while group 36-40yrs had 26 subjects. For GHB, group 21-25yrs had 86 subjects; group 26-30yrs had 74 subjects; group 31-35yrs had 28 subjects while group 36-40yrs had 12 subjects.

2.5 Sample Collection

The subjects were well-positioned and a tourniquet was tied at the upper arm to expose cubital veins. The sample collection site was cleansed with 70% ethanol using a cotton wool swab. A 5ml sterile syringe was used for the collection of blood by venipuncture into EDTA bottles, mixed and labeled. The procedure was repeated for all subjects. Site was cleaned with a dry cotton swab.

2.6 Malaria Determination (Thick and Thin Film)

2.6.1 Making of thick film

A thick blood film was made by pipetting 12ul of blood onto a clean grease-free slide 1cm away from the edge of the slide and spread with a spreader slide to make a thick smear. The slides were air-dried.

2.6.2 Making of thin film

A thin film was made by pipetting 3ul of blood onto a clean grease-free slide 1cm away from the edge of the slide. A clean spreader slide held at an angle of 45 degrees was placed on the drop of blood and the blood was allowed to spread along the entire width of the spreader slide. The spreader slide was pushed forward rapidly and smoothly to obtain a feathered edge.

2.6.3 Giemsa staining technique for thick and thin film

2.6.3.1 Working solution

The stock Giemsa solution was diluted 1 in 10 (10%) in buffered distilled water of pH 7.2. The thin film was fixed in methanol for 2mins and allowed to dry by evaporation. All the slides were placed on a staining rack and flooded with 10% Giemsa stain using a pipette for 30 minutes. The stain was gently flushed off the slide by adding drops of clean water while avoiding tipping off the stain to avoid leaving deposits of scum over the film. The slides were placed film side downwards on a slide rack to drain and dry ensuring the film does not touch the rack [14].

2.6.3.2 Microscopy and parasite density estimation

The thick and thin films were examined microscopically using immersion oil and x 100 objectives. The number of parasites against 100 white blood cells was counted and recorded. The number of the parasite was calculated using a standard formula:

\[
\text{Standard white blood cell count} \times \text{number of parasites} = \text{parasite}/\mu\text{l of blood}
\]

2.7 Statistical Analysis

The data were analyzed statistically using chi-square test to test for independence among the categorical variables at α level of 0.05 (level of significance).

3. RESULTS

Table 1. Prevalence of Malaria by Age Groups among Pregnant Women in Braithwaite Memorial Specialist Hospital (BMSH), Port Harcourt and General Hospital (GHB), Bori

Table 1. showed the age base prevalence of malaria in BMSH and GHB. For both health facilities, subjects were grouped in four groups; 21-25yrs, 26-30yrs, 31-35yrs and 36-40yrs. In BMSH, the age group with the highest prevalence was 21-25yrs while the age group with least prevalence of malaria was 31-35yrs. In GHB, the age group with the highest prevalence was 21-25yrs while the age group with least prevalence of malaria was 26-30yrs.

4. DISCUSSION

The study was 400 pregnant women were selected and grouped according to their age class. The age classes or groups were 21-25yrs, 26-30yrs, 31-35yrs and 36-40yrs. From the table presented above, it is observed the age group of 31-35yrs had the highest number (80 subjects) of pregnant women and second to group 26-30yrs in BMSH. While in GHB, it was observed that the age group with the highest number pregnant women was group 21-25yrs, having 86 subjects and the number dropped as year increases. This could mean that women in the sub-urban area of Bori were prone to early marriage which is often the case in rural and semi-urban areas where interest for education and career development are low. On the other hand, women in urban (BMSH) were prone to late marriage probably due to their desire to attain certain level of educational status before conceiving the thought of marriage.

Among the age groups, the prevalence of malaria was highest in 21-25yrs in both health facilities, amounting to 36.4% and 44.2% for BMSH and GHB respectively. This implies that early pregnancy or pregnant women of a young age are more prone to suffer from malaria parasitaemia than older age groups. It could also be a result of acquired immunity by older mothers to malaria infections due to previous exposures. This result agrees with the work of Uneke et al., [15] of Abakiliki, South Eastern Nigerian which recorded that the most infected pregnant women were those of age group 20 – 24 years (20.8%) and Wogu et al., [16] (30%). Also, a study conducted by Gontie et al., [6] reported that young pregnant women were more exposed to malaria with higher parasite densities than older age pregnant women. This could be attributed to increased awareness of the disease, prevention, and more exposure to health care services by older mothers. Contrarily, the finding from this study did not agree with the study by Adam et al., [17] which reported that age had no significant effect on the prevalence of malaria parasitemia among pregnant women.

The marked prevalence of malaria seen in GHB pregnant women compared to their counterpart subjects of BMSH may be due to increased exposure to mosquito bites by way of farming, trading and other socio-cultural activities. In BMSH, the prevalence was lower and the reason could be that these women have better awareness of the transmission of the parasite and seek medical treatment when they feel sick and perhaps due to the socio-economic status, they could afford medical bills. The result of this study is a reflection of exposure patterns among the various age groups and disagrees with findings from Eastern Sudan which reported that age was not significantly associated with malaria during pregnancy [17].

5. CONCLUSION

This study has shown that younger pregnant women within the age bracket of 21-25yrs are more vulnerable to malaria parasitaemia than older age groups in Rivers State.

ETHICAL APPROVAL

Ethical clearance was obtained from Ethics committee of Rivers state Ministry of Health. Subjects gave their written consent prior to recruitment into the study.
